

HARTLESS JOE PROPERTY

The 100% owned Hartless Joe property covers high-grade epithermal gold-silver mineralization in southern Yukon Territory. The property is located 28 km east-northeast of Whitehorse within the traditional territories of the Ta'an Kwäch'än Council and the Kwanlin Dün First Nation.

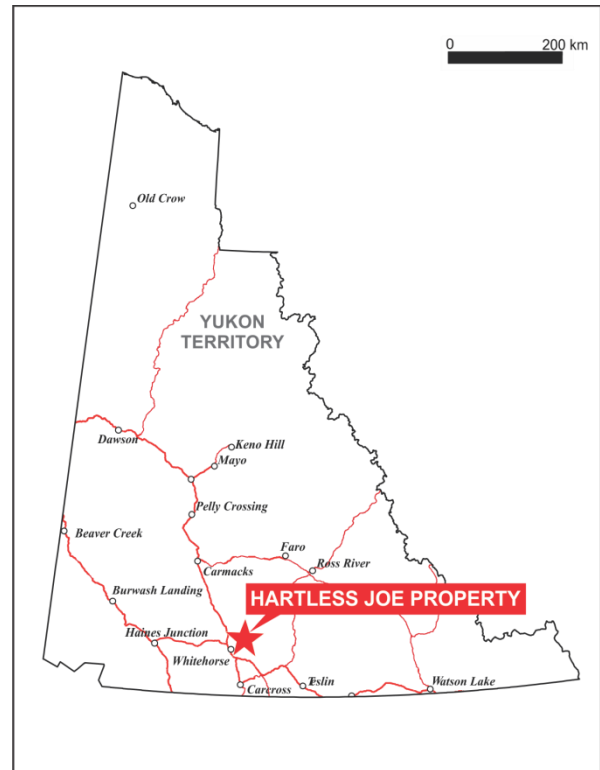

The Hartless Joe property lies within Stikina, an accreted island arc terrane that extends through northern British Columbia into Yukon. Stikina hosts important epithermal vein and exhalite deposits such as the Premier Mine, Brucejack Deposit and Eskay Creek Mine.

In 2015, Strategic discovered a high grade quartz-rich band that is either an exhalite horizon or a flat-lying vein on the lower slopes of an alpine valley, within a 500 by 250 m area containing scattered mineralized talus and strong gold and copper soil geochemical anomalies. A continuous chip sample taken across the discovery

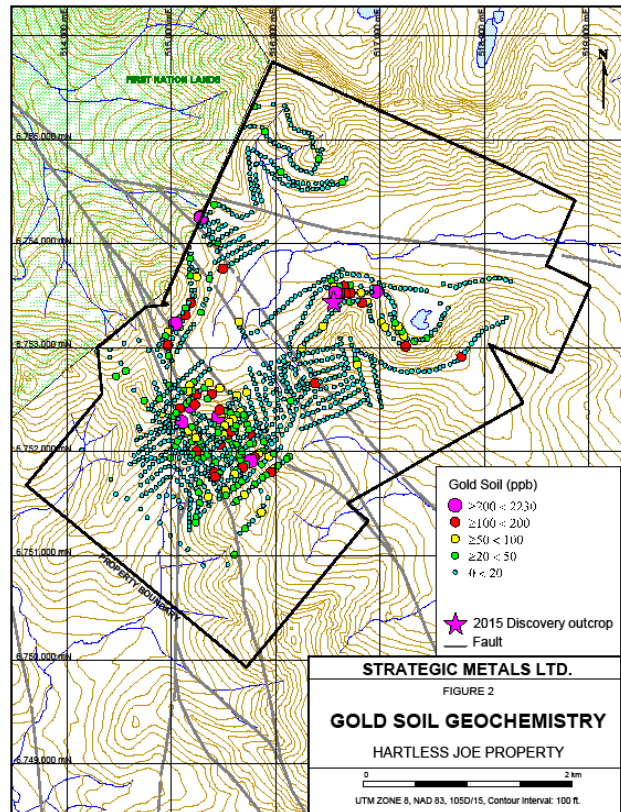

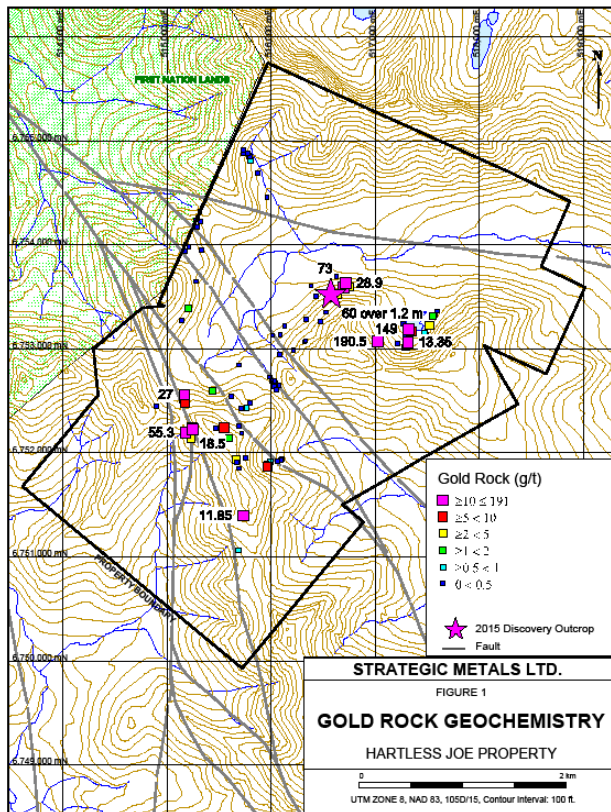

outcrop graded **60 g/t gold, 554 g/t silver, 5.01% lead, and 0.35% copper over 1.2 m**. No

Hand sample from the discovery outcrop

follow-up prospecting or soil sampling has been done in the vicinity of the new discovery. Other particularly noteworthy results from the immediate area include: 73 and 28.9 g/t gold from quartz-rich rock samples taken 140 and 180 m northeast of the discovery outcrop, respectively; and, strongly anomalous soil geochemical values for gold (100 to 1440 ppb) and copper (200 to 985 ppm). The area of interest is open to extension on mostly overburden covered hillsides.

Reconnaissance-scale exploration conducted in different parts of the Hartless Joe property has identified several areas with gold-rich mineralization and highly elevated soil geochemical results for gold and its various pathfinder elements. Gold occurrences and soil anomalies are spread over a 5.4 km² area (see Figures 1 and 2). A total of 108 rock samples have been collected from the property to date, with 28 of them grading better than 1 g/t gold and 10 assaying more than 10 g/t gold (including values of 149 and 190.5 g/t). Soil results are also highly encouraging with 36 of 1064 samples returning between 100 and 2230 ppb gold. None of the exploration targets on the Hartless Joe property have been mapped and prospected in detail.

The Hartless Joe property is well located geologically and logistically, and offers excellent potential to host a high-grade gold deposit. The next phase of exploration at the property should consist of property-wide geological mapping, prospecting and soil geochemical surveys and intensive prospecting and hand trenching near the 2015 discovery outcrop. Once the orientation, character and size potential of the mineralization is confirmed at surface, a helicopter-supported diamond drill program should be undertaken to evaluate its three-dimensional continuity.
